Optimization and matching exercises

DM13-E01

Give a source-reachable graph with a negative edge but no negative cycle where ordinary Dijkstra finalization returns a wrong distance.

DM13-E02

On A, B, C, D with AB:1,AC:4,BC:2,BD:5,CD:3,find an MST and verify at least one edge by the cut property.

DM13-E03

Build a three-job/three-worker bipartite graph failing Hall. Exhibit the deficient subset and a maximum matching.

DM13-E04

Add source/sink to a unit-capacity bipartite reduction and prove that an integral maximum flow's used L→R arcs form a matching.

DM13-E05

For capacities sa:3,sb:2,ab:1,at:2,bt:3,find maximum flow, minimum cut, and final residual reachable set.

DM13-E06

Explain what can go wrong if Kruskal adds minimum-weight edges without cycle checks and how DSU repairs it.

DM13-E07

Use source A and arcs A→B:3,A→C:1,C→B:1,B→D:2,C→D:7,D→E:0,B→E:6,with isolated F. Trace every Dijkstra distance, finalized set, and predecessor. Recover the path to E and verify every arc inequality. Would adding a negative self-loop at F alter these A-distances? Distinguish a negative cycle's existence from source reachability.

DM13-E08

For a finite connected loopless undirected graph, prove a spanning tree T is the unique MST iff every nontree edge is strictly heavier than the heaviest edge on its T-path. For cycle A–B–C–D–A with all cycle weights one and diagonals AC, BD of weight two, list every MST and identify edges appearing in all of them.

DM13-E09

Add original ba of capacity two to the text's unit-capacity sa, sb, ab, at, bt network. First augment s–a–b–t by one. List the two b→a residual records and capacities. Then augment s–b–a–t by one using either original ba or reverse ab. Give both resulting original-flow vectors, values, and optimum certificates.

DM13-E10

Let a, b, c each neighbor 1,2 and d only neighbor 3. Find maximum matching, Hall deficiency, and a minimum cover from alternating reachability, listing each reachable set. Add right vertex four and edge c4;find a new maximum matching and minimum cover.

DM13-E11

Left i has integer demand $d_i \geq 0$ and right j capacity $b_j \geq 0$. Allowed pairs may carry multiple units. Prove all demands are feasible iff every $S \subseteq L$ has $d(S) \leq b(N(S))$,using a full source–left–right–sink cut proof. Solve d=(2,1),b=(1,2),where the first left vertex neighbors both right vertices and the second only the first. Is the same condition sufficient if each pair is limited to one unit?
